

Example: Consider an infinite sequence of trials that are independent, a trial succeeds with probability  $p$  or fails with probability  $1-p=q$ . Let  $X$  be the # of trials until 1st success. So  $X$  is a positive, discrete random variable. In fact  $X$  is integer valued.

Mass of  $X$ :  $p(x) = P(X=x) = q^{x-1} \cdot p$

CDF of  $X$ :  $F_x(x) = P(X \leq x) = P(X=1) + P(X=2) + P(X=3) + \dots + P(X=x)$   
 for integers  $x$ .  
 $= p + pq + pq^2 + \dots + pq^{x-1}$   
 $= p(1 + q + q^2 + \dots + q^{x-1})$   
 $= (1-q)(1 + q + q^2 + \dots + q^{x-1})$   
 $= 1 - q^x$

plot the mass  $p_X(x)$

plot the CDF  $F_X(x)$
